ELECTRONIC ENERGY METERS

INTRODUCTION

The energy meter is an electrical measuring device, which is used to record Electrical Energy Consumed over a specified period of time in terms of units.

PRODUCT USES AND SPECIFICATIONS

India is currently witnessing a revolution in the field of electricity measuring where electronic energy meters are fast replacing the conventional Ferraris meters. Energy measuring is essential at all places where electricity is consumed. i.e. at homes, offices, farms, workshops, shops, factories etc. The most important customer groups for these meters are the State Electricity Boards (SEBs) and private electricity supplying companies. The Electronic Energy meters are rugged, reliable and easy to calibrate. Unlike the conventional energy meters, the electronic energy meters do not have any moving parts. The current and voltage is sensed electrically and the power consumed is computed using electronic logic circuits. Electronic energy meters have a very good in the country. This is primarily due to drivers such as rural electrification, power sector reforms (deregulation process being vigorously implemented by federal and State Governments), the formation of privately-owned distribution companies with a mandate to improve revenues and efficiency in system operations, and to improve customer satisfaction.

Electronic Electric meters have an advantage over conventional electromechanical meters due to reason such as

1. Compactness
2. Ruggedness and reliability
3. Good accuracy
4. Computation of current and maximum demand

5. Detection and recording of tamper, peak load and maximum demand violations
6. Power quality measurement
7. Multi-tariff programming
8. Electronic energy meters come in different types depending on their application.

| Sl No | Type | Application | Capacity |
|--------------|--------------------|---|-----------------|
| 1 | Single phase meter | Mainly deployed in domestic applications(homes, shops, etc) | 5-60A |
| 2 | 3-phase meter | KWh and KVA measurement –Mainly deployed in agricultural sector. | 10-80A |
| 3 | 3-phase meter | KWh, KW,KVA.V/ph,1/ph,pf, frequency measurement- Mainly deployed for light industrial and commercial applications | 10-80A |
| 4 | 3-phase meter | KWh, KW,KVA.V/ph,1/ph,pf, frequency measurement, load survey, multi tariff, time of use features= used in heavy industrial applications | 10-80A |

MARKET

Every house, small factory, business establishment, shops, offices etc. need at least one energy meter to register power consumption. The supplier of electrical raises the bill on the basis reading shown by this meter. The producers of electricity sale the electricity to the electricity boards and boards have to sale this energy to the consumer. Consumer needs to pay the amount against the bill raised by the supplier. The data generated by the energy meter is the base to raise the bill by power supplier. Because of massive rural and urban electrification programme of Government, there is a good demand for this product. This product is available in single phase and three phases at different current rating as

per customer's requirement. Though, newly developed electronic energy meter is also available in the market but in view of simple technology involved to manufacture this product and for replacement of spare parts, the present demand and future prospect of this product is reasonably good.

The Indian power sector has grown from a low 1300 MW at the time of independence to more than 138,000 MW. In terms of growth, the generation rate is slightly more than 8 per cent. In spite of this growth, the country as a whole suffers from black outs and brown outs with large parts of the population (more than 500 million) without access to power. The country faced a peak load deficit of 13.9 per cent and a supply deficit of 9.9 per cent in 2006-07.

The Indian economy has grown at an average rate of 8.4 per cent per annum in the Tenth Five year plan. This has catapulted the country into the world's big league, and on the basis of purchasing power parity, today it is ranked as the fourth largest economy, behind the U.S., China and Japan. From various projections, in absolute terms, India will be one of the top three economies in the world in the next 25 years.

While the economy has grown and India is today spoken of in the same breath as China, the power sectors in the two countries present quite divergent pictures. In 1950, the installed capacities of China and India were at the same level. Thereafter, while India could achieve an installed capacity of 138 Giga Watts (GW) at the end of 2006, China had an installed capacity of 620 GW.

During 2006 alone, China added more than 100GW of new capacity. Compared to this, during each of the last three five year plans on an average, India could add only 20 GW. Further, per capita consumption of electricity in China stands at 1440 KWH, whereas in India it is only 630

KWH. Also, considering the fact that large parts of the Indian population do not have access to electricity, it becomes clear that the power sector has to put in lot of effort.

The Eleventh Plan envisages a capacity addition of around 80000 MW for which ordering has been completed. BHEL has got 55 per cent share of the orders. Integrated energy policy envisages coal to remain the dominant fuel source till 2031-32. To bring the per capita consumption to world average level, four-fold growth is required of which the share of nuclear power will go up significantly. McKinsey estimates demand to soar from around 148 GW at present to 315-335 GW by 2017.

To achieve these targets, the development of mega projects becomes a necessity. With a view to encouraging large size projects, the Central Government enunciated the mega power policy in 1995, which provided tax incentives to projects above a certain size that cater-participation of private players, the Government formulated the Ultra Mega Power Project (UMPP) policy in 2005, which envisaged the setting up of projects of 4000 MW capacity each. The developers for these projects were to be selected through a tariff based competitive bidding process. Three projects have been awarded under this policy and these are expected to be completed in 5-6 years.

India has an installed capacity (including captive) of less than 150,000 MW and has one of the lowest per capital consumption in the world (around 600 units a year as compared with a global average of over 2600 units and China's at 1100 units). Added to this is the harsh reality that only 55 per cent of the households across the country have access to electricity and more than 1.25 lakh villages are still to be electrified!

The abovementioned discussion points to the necessity of creation of additional capacity of power and the installation of more sub stations and transmission towers. There is tremendous scope and backlog to be fulfilled urgently in this sector.

INSTALLED CAPACITY

| 10 | Variacs (4A) | 2 | 0.10 |
| 11 | Bench Drilling Machine | 1 | 0.10 |
| 12 | Portable grinder | 1 | 0.10 |
| 13 | Tools/jigs/fixtures | | 0.20 |
| 14 | Assembly line (conveyors) | | 0.30 |
| 15 | Testing Machines | | 3.00 |
| | | | 30.00 |

MANUFACTURING PROCESS

The five basic Components of and electronic energy meter are input sensors, power supply, energy measurement module display (counter) and passive components.

An electronic energy meter transforms the load current and line voltage to a usable form. Current sensors such as shunts or current transformers (CTs) are used to transform current to a voltage proportional to current at the interface with the energy meter. Parameters such as power consumption, heat dissipation, quality and performance over a wide current dynamic range have to be considered when choosing a suitable current sensor. The meter also includes a voltage sensor such as a potential transformer (PT) or a resistive divider. The resistive divider attenuates the line voltage to an acceptable input voltage for the energy measurement LC.

In the heart of an electronic energy meter is an energy measurement LC, a fixed function DSP that calculates watts and accumulates watt-hours. The energy measurement LC, interfaces with a chosen sensors, accurately calculating the power and interfacing with an external display.

The external display of an energy meter can either be mechanical and electronic in nature. A Stepper motor counter is used for mechanical counter, while a digital counter and liquid-crystal-display,(L.C.D) are examples for electronic display. An advantage of using an LCD display is that such a meter can display more than one type of information at a time. For example, the display could include power information in watts, KWh, apparent power (VA) power factor (PF) and/or/meter temperature. The drawbacks are that LCDs are significantly more expensive than stepper motor counters and require non-volatile memory to store data in the event of power shutdown.

Passive components such as resistors, capacitors, light emitting diodes (LEDs), and jumps are used in the attenuation, power supply and calibration network. The manufacturing of electronic energy meters is an assembly process involving the sensors electronic circuits and display unit. In the electronic assembly the ICs, transistors, diodes, resistors, capacitors,transformers,coils,relays, potentiometers and laid on the PCB and soldered. The soldering is done either manually or using wave soldering machines. The assembled PCBs are tested for performance. Subsequently the electronics assembly along with hardware such as connectors, switches, terminals display, are assembled and housed in a polycarbonate casing. An attractive front panel (or fascia) is fitted on the casing.

The testing process of the most critical in the entire manufacturing process. The electronic energy meter is tested and calibrated to the desired specification on the testing assembly using standard voltages and currents. Endurance, impulse, climatic, vibration, shock, harmonics and ingress protecting testing ensure the reliability of the electronic

energy meter. After testing and calibration, the equipment is packaged and ready for dispatch.

QUALITY AND STANDARDS

Bureau of Indian Standards specified IS 13779/IEC -1036 is the most widely followed standard by the manufacturers of Electronic Energy Meters in India. This standard lays down the range of accuracy as per class 1.0,0.5 and 0.2.

RAW MATERIALS

The basic raw materials used for manufacturing of electric energy meters are

| | |
|---|---|
| Current Transformers (CT) | Potential Transformers (PT) |
| Integrated Circuits (ICT) | Components (diodes, transistors, resistors capacitors, potentiometer, rectifiers, transformers switches filter etc) |
| LCD display panels | Wires and Connectors |
| Housing material (Polycarbonate easing) | Consumables (solder) |
| Packing material | Printer Circuit boards (PCBs) |
